Abstract

BACKGROUND: The nucleotide changes in different genetic loci increased the incidence risk of breast cancer.

AIM: The aim of present study was to investigate genotype distribution at codon 72 of the TP53 gene (rs1042522) in breast cancer patients to achieve a potential diagnostic marker related to some demographic feathers.

METHODS: In our case-control study, blood samples were collected from a total of 34 patients harboured breast cancer. DNA was extracted, and nested-PCR was performed. Products were digested with AccII and subsequently were sequenced. Results were compared with samples characteristics.

RESULTS: The PCR results indicated the correct implementation of extraction and amplification protocol. The genotypic distribution at codon 72 of TP53 in control group was 20%, 62.4% and 16.6% for Arg/homozygous, 50% heterozygous, and 26.47% homozygous variant. The absence of Arg at codon 72 of TP53 is relevant with age higher than 40 years and changes in different codons of the genes, including BRCA1, BRCA2, and TP53 etc. increase the risk of developing breast cancer. In some cases due to a tumour extends to the underlying muscles of the chest wall or skin, BC is type III. This Stage also includes BCs involving inflammatory system, in which case the breast is red or swollen [4], [5], [6]. BC stage IV refers to tumours that metastasise to the outside of the breast and the lymph nodes, as well as to the brain, bones, skin, and other organs. The basics of cancer genetics is the occurrence of changes in signalling pathways and genes regulatory networks [5]. Changes in different codons of the genes, including BRCA1, BRCA2, and TP53 etc. increase the risk of developing breast cancer.

Introduction

Breast cancer (BC) is one of the most common types of cancer that causes mortality rates each year. Despite advances in early diagnosis and proper treatment for this disease, it remains the main cause of death among women [1], [2], [3]. The most common sites of BC metastasis are bones, lung and liver. Metastasis of BC to the brain less occur. The growth of cancer cells in BC is considered in three stages. BCs stage I or II are in the initial stage. If the tumour extends to the underlying muscles of the chest wall or skin, BC is type III. This Stage also includes BCs involving inflammatory system, in which case the breast is red or swollen [4], [5], [6]. BC stage IV refers to tumours that metastasise to the outside of the breast and the lymph nodes, as well as to the brain, bones, skin, and other organs. The basics of cancer genetics is the occurrence of changes in signalling pathways and genes regulatory networks [5]. Changes in different codons of the genes, including BRCA1, BRCA2, and TP53 etc. increase the risk of developing breast cancer.

mutation in TP53, the occurrence of BC can be accompanied by brain tumours and leukaemia. TP53 (also known as BCC7, LFS1) is a TSG. This gene is encoded on the human chromosome 17 at position p13.1 (HGNC ID: 11998). Different transcripts are reported for this gene (Figure 1). Some of these transcripts are not protein coding (ENSG00000141510). This gene is very important in the coordination of the cell cycle as well as in preventing the development of cancer [2].

Materials and Methods

In present case-control study, samples were collected from Ayatollah-Khansari hospital in Arak city. This study was performed between November 2016 and June 2017. A total of 34 pathological and clinical data were classified for the collected breast cancer samples (median age: 48 years). Also, normal samples from non-tumour individuals were equal numbers of patients group. Three ml of blood was collected from each sample in CBC test vial. The study was approved by the Research Ethics Committee of Arak University of Medical Sciences (Ethics number 618B/3090). Participants of present study agreed with and signed a consent form.

DNA extraction was performed from 500 μl whole blood using the Diatom DNA Kit (IsoGene, Moscow, Russia) based on its instruction. Samples were loaded on 1% agarose gel, (YTA, Iran).

In Polymerase chain reaction, 50 mM MgCl2 (Cinagene, Iran), 10X Buffer (Cinagene, Iran), 10 mM dNTP (Cinagene, Iran), 1 unit Taq polymerase (Cinagene, Iran), and specific primers at a suitable concentration of 10 pmol were used. Annealing temperature for the primers [9] was optimised at 52.7°C.

In this study, PCR products of the first stage were used in a thermocycler machine (Eppendorf, Germany) as a template in the second stage PCR using a pair of internal primers in order to more specificity and enhancing the amplified bands. A non-template sample was used as a negative control. The sequence of these primers is shown in Table 1.

Restriction enzyme digestion was performed by Accl (Vivantis, Malasia) at 37°C for 3-16 hours. Production of one fragment of 300bp indicated the presence of the wildtype allele (Arg). The presence of the variant allele (Pro) was determined by the observation of two fragments of 160 bp and 140bp. The produced amplicons were sent for sequencing. The sequencing was carried out with the ABI Applied Biosysytem machine-Model 3730XL (Macrogene, Iran).
South Korea). Sequencing results were analysed using Chromas, Mega 4.0, Blast and Blat software.

Validation of genotypes was evaluated by comparison of sequences results with data banks such as UCSC. Chi-sq Hardy-Weinberg equilibrium (HWE) test calculator were used for biallelic markers including SNPs. The difference between the groups was determined by one-way ANOVA GraphPad prism 7.0. P values less than 0.05 were considered statistically significant.

Results

The results of the amplification reaction indicated the accurate of the extracted DNA, the correct implementation of the temperature protocol and used primers. Figure 2 shows the 300bp amplicon of the TP53 gene.

![Figure 2: Steps of Nested-PCR steps in this study. The yellow arrow shows the 300 bp amplicon of TP53 gene](image)

In below figure columns 1-4 indicated bands of heterozygous samples that have three bands (300, 160 and 140 bp). Also, Figure 3b shows the sequence analysis of the 8 homozygous amplicons.

![Figure 3: A) Agarose gel of digestion reaction. Column 1-4 showed heterozygote samples (Arg/Pro) and column 5 showed a homozygote wildtype (Arg); B) Nucleotide sequences from the sequencing of clinical samples (Chromas and Mega4 software)](image)

The genotypic distribution in the patient group was 23.52% homozygous wildtype (Arg), 50% heterozygous (Arg/Pro), and 26.47% another homozygous variant (Pro). These genotypes in the control group were 20%, 62.4% and 16.6% for homozygous wildtype, heterozygous and homozygous variant respectively.

The C allele freq = 0.48; G allele freq = 0.52 was the frequency of changes in codon 72 of the TP53 gene in patient group (HWE calculator, p < 0.05). The Chi-square in control group was not significant (X² = 6.8, p > 0.05).

The Figure 4 showed that there are a significant association between the changing at codon 72 (Arg72 Pro) of TP53 gene sequences and the Age > 40, BMI > 22, WHR > 0.8, metastasis to other organs, positive ER and PR status and less response to chemotherapy in BC samples than the control group. These associations are statistically significant.

Discussion

The incidence rates of BC increase with an ascending trend so that its frequency has doubled over the past 20 years. In Iran, BC is the most common type of cancer after stomach and oesophagus cancers. Therefore, diagnosis at first stages and study of the molecular mechanisms of BC are necessary [1], [2], [3]. Molecular events that regulate cell survival, apoptosis, growth and differentiation of the cell, played an important role in the overall kinetics of tumour growth as benign or malignant [14]. Mutation of TP53 is the most common genetic change in human cancers and is associated with poor response to treatment including

chemotherapy and radiotherapy. Recent studies have shown the probably beneficial and valuable effects of gene therapy with the goal of TP53 as a complementary therapy in cancers. Studies in 1997 and 1998 found that p53 plays a critical role in controlling of the cell cycle since its normal function not forces the cell to stop the cell cycle so that it can enter a period of interruption to repair the DNA damage. If the cell could not repair damage to the cell, it would commit suicide to prevent mutations in the cells [6], [7]. Injury to the TP53 gene occurs during the life-span of the individual, but in rare cases, involved about 1% the cases of sporadic BCs [15], [16], [17], [18]. In a study in 2009, numbers of 1836 articles from 1986 to 2008 were reviewed for involved genes in BC [3]. In the TP53 gene, the importance of codon 72 has been shown to identify changes in the various populations. This codon site is within the active site of the p53 protein. In studies conducted in 2006 and 2007, it was found that using some of the pathological characteristics of BC, such as the tumor size, negative status of PR, positive status of the lymph nodes and high differentiation can be predicted that a patient will be more likely to develop metastasis [19], [20], [21], [22]. Other studies showed significant differences in the prevalence of codon 72 in TP53 polymorphism in endometriosis in a Brazilian population [23].

The present study showed that the frequency of changes in codon 72 of the TP53 gene in the studied population was common and totally 76.7 % of the studied patients had this change. Also, there are associations between a polymorphism at microRNA binding site in BRCA2 with BC susceptibility [24], [25]. Also, there is an association of polymorphisms in FCGR2A and FCGR3A with a degree of Trastuzumab in the Adjuvant treatment of ERBB2/HER2- positive BC [26]. A study results at 2017 showed a significantly association between six SNPs including FGFR2 (rs2981582), HCN1 (rs981782), MAP3K1 (rs889312), TOX3 (rs3803662), ZNF365 (rs10822013), and RAD51B (rs3784099), with breast cancer risk [25]. A study in South Korea on patients with gastric cancer that treated with cisplatin and paclitaxel chemotherapy indicated that rs1042522 (G/G and C/G) genotypes compared to rs1042522 (C/C) were significantly associated with lower response rate to the chemotherapy treatment (35.7 vs. 66.7%, p-value 0.019) [28]. Another study at 2014 on patients with NSCLC showed that G/G genotype of rs1042522 was more resistant to the first-line chemotherapy drugs, such as cisplatin [29]. In the present study, we evaluated all changes in studied amplicon compared to the control samples by sequencing method. The results of our study indicated the relationship between the rs1042522 polymorphism with age, BMI, metastasis, positive status of PR and ER and treatment response rate in these patients (Table 3).

In the present study, we investigated that rs1042522 SNP may be associated with susceptibility to BC among Iranian women with higher age and BMI. The distribution of C Allele in individuals with age of higher than 40 years was 1.2 times more than lower ages. Also, the frequency of G allele is associated to lower BMI and WHR. Our data showed there was a direct association between C/G and C/C genotype of rs1042522 with a negative response to chemotherapy (1.13 times).

Based on the new issue of “personalised medicine” in modern medicine, patients can be treated according to their molecular feathers. Therefore, it can be inferred that determination of TP53 variants for BC patients is suitable before the starting the treatment protocol. Cancer is a multi-factorial disease and, in addition to genetic, environmental factors such as smoking, family income also etc. contributes to its development. The results of this study revealed the lack of significant correlation between these factors including family income, Educational level, the age of marriage and cigarette smoking with the studied polymorphism (data not shown). However, any of these factors may be effective in the overall survival rate and severity of the disease.

However any of these factors may be effective in overall survival rate and severity of the disease. Performance of molecular diagnostic tests for the evaluation of cancer genes in medical centers is critical. Hence, the determination of polymorphism in the mentioned codon can be used as a potential candidate diagnostic marker for high risk BC.
